Painlevé solution of an integral equation

Y.Y. Atas, E. Bogomolny
Univ. Paris Sud, CNRS, LPTMS, UMR8626, Orsay F-91405, France

Abstract. It is demonstrated that a certain integral equation can be solved using the Painlevé equation of third kind. Inversely, a special solution of this Painlevé equation can be expressed as the ratio of two infinite series of spheroidal functions with known coefficients.

1. Introduction

We consider an integral equation in a finite interval for unknown function $g(t)$

$$
\int_{-1}^{1} K(|x-t|)g(t)dt = f(x)
$$

where kernel $K(w)$ has the form

$$
K(w) = w^{\nu} K_{\nu}(\theta w).
$$

Here $K_{\nu}(w)$ is the modified Bessel function of the third kind which obeys the equation

$$
K_{\nu}''(w) + \frac{1}{w}K_{\nu}'(w) - \left(1 + \frac{\nu^2}{w^2}\right)K_{\nu}(w) = 0
$$

and exponentially decreases at large argument

$$
K_{\nu}(w) \xrightarrow{w \to \infty} \sqrt{\frac{\pi}{2w}} e^{-w}.
$$

At small $w$

$$
K_{\nu}(w) \xrightarrow{w \to 0} 2^{\nu-1} \Gamma(\nu) w^{-\nu} + 2^{-\nu-1} \Gamma(-\nu) w^{\nu} + O(w^{2-|\nu|}).
$$

We restrict the discussion to the case $|\nu| < 1/2$ though certain results could be generalized to all $\nu > -1/2$.

Equation (1) with kernel (2) appeared in some physical problems. For example, it describes forced convection heat transfer and contact problems in elasticity (see [1, 2] and references therein). The particular case of (1) with $\nu = 0$ and imaginary $\theta$ gives the solution of the wave scattering problem with the Dirichlet boundary conditions at the strip $[-1, 1]$ (see e.g. [3]).
In [1] the solution of this equation has been represented as a series of the spheroidal functions which generalizes the expansion in terms of Mathieu functions for the case \( \nu = 0 \) obtained in [4]. Equation (1) belongs to the class of equations whose particular solutions can be obtained by Latta’s method [5] but the resulting equations contain unknown constants. For \( \nu = 0 \) these constants have been explicitly calculated by Myers [6] through a solution of the Painlevé equation of third kind (a concise summary of Myers’ result is given in Appendix B of [2]).

The purpose of this note is to show that methods used for \( \nu = 0 \) can be generalized for non-zero \( \nu \) (\( |\nu| < 1/2 \)) and special solutions of (1) can be obtained from ordinary differential equations (ODE) using the Painlevé III equation more general than the one discussed in [6]. As a by-product we obtain an explicit formula for a solution of the Painlevé III equation as a ratio of two infinite series of spheroidal functions with known coefficients.

The plan of the paper is the following. In Section 2 we use Latta’s method to obtain a system of ODE in \( t \) variable for two special solutions of (1) corresponding to the right-hand side of (1) equals \( \cosh \theta x \) and \( \sinh \theta x \). These equations contain certain constants which are determined in Section 3 by deriving the second system of ODE with respect to variable \( \theta \). The condition of the compatibility of these two systems of equations leads to the Painlevé III equation for the constants. The limiting behaviour of necessary quantities for small and large \( \theta \) are derived in Section 4. Though the discussed methods work only for the above mentioned particular choices of the right-hand side of (1), in Section 5 it is demonstrated that the knowledge of these special solutions permits to investigate more general problems. In Section 6 we show that kernel (2) is a positive-definite function which leads to the boundedness of the discussed Painlevé III solution at positive arguments. For completeness, in Appendix A the series expansion of solutions of integral equation (1) is present and in Appendix B properties of spheroidal functions are briefly described.

2. First system of equations

The method of Latta [5] can be applied for integral equations of the form (1) when its kernel, \( K(w) \), obeys a differential equation whose coefficients depends linearly on \( w \). The kernel \( K(w) \) determined in (2) obeys the equation

\[
wK''(w) + (1 - 2\nu)K'(w) - w\theta^2 K(w) = 0
\]

so the application of Latta’s method is straightforward.

Let us define the integral operator corresponding to (1)

\[
(\Gamma g)(x) \equiv \int_{-1}^{1} K(|x - t|)g(t)dt
\]

and its two particular solutions, \( g_c(t) \) and \( g_s(t) \), with the right-hand side equals \( \cosh(\theta x) \) and \( \sinh(\theta x) \)

\[
(\Gamma g_c)(x) = \cosh(\theta x) , \quad (\Gamma g_s)(x) = \sinh(\theta x) .
\]
It is plain that parities of \( g_{c,s}(t) \) are fixed: \( g_c(-t) = g_c(t) \) and \( g_s(-t) = -g_s(t) \).

An important ingredient of Latta’s method is the uniqueness of the solution: when \( f(x) = 0 \) the only solution of (1) is \( g(t) = 0 \). For kernels like (2) it is known that if \( f(x) \) belongs to \( L_2(-1,1) \) then the solution is unique. A simple way to prove it is to use the expansion into a complete set of functions as in Appendix A.

Changing in (6) variable \( w \) to \( x-t \), multiplying the resulting expression by \( g(t) \), and integrating over \( t \in [-1,1] \) gives the following identity (the first Latta equation)

\[
(\Gamma tg)"(x) - \theta^2(\Gamma tg)(x) = x[(\Gamma g)"(x) - \theta^2(\Gamma g)(x)] + (1-2\nu)(\Gamma g)'(x) = 0
\]

which permits to calculate \((\Gamma tg)\) when function \( f(x) \equiv (\Gamma g)(x) \) is known and obeys the equation \( f" - \theta^2 f = 0 \).

The second Latta equation is obtained by remarking that the kernel in (1) depends only on the difference of arguments. Therefore, it is easy to check that for arbitrary function \( y(t) \) such that \( y(\pm1) = 0 \)

\[
(\Gamma y)'(x) = (\Gamma y')(x).
\]

To apply this equation it is necessary first to determine the behaviour of function \( g(t) \) near ends of the strip, \( t = \pm1 \). Collecting the most singular terms as it is done in Section 4 or using the representation (A.5) gives

\[
g_{c,s} \to_{t \to 1} k_{c,s} \frac{1}{(1-t)^{\nu+1/2}}.
\]

Therefore when \( \nu < 1/2 \) functions

\[
y_{c,s}(t) = (1-t^2)g_{c,s}(t)
\]

are zero at the both ends of the strip, \( y_{c,s}(\pm1) = 0 \) and (10) is valid for them.

Equations (9) and (10) permit to derive ODE for special solutions (8) as follows. By definition

\[
(\Gamma g_c)(x) = \cosh \theta x.
\]

From (9) it follows that \( y = (\Gamma tg_c) \) obeys the equation

\[
y" - \theta^2 y = (1-2\nu)\theta \sinh \theta x
\]

whose odd solution is

\[
y \equiv (\Gamma tg_c)(x) = \frac{1-2\nu}{2} x \cosh \theta x + A \sinh \theta x
\]

where \( A \) is a constant independent on \( x \).

In exactly the same manner the knowledge of \( \Gamma tg_c \) permits to calculate \( \Gamma t^2 g_c \)

\[
(\Gamma t^2 g_c)(x) = \frac{(1-2\nu)(3-2\nu)}{8} x^2 \cosh \theta x + x \sinh \theta x \left(\frac{1-2\nu}{2} A - \frac{1-4\nu^2}{8\theta}\right) + C \cosh \theta x
\]
where $C$ is another constant.

Similarly, with certain constants $B$ and $D$

\[(\Gamma g_s)(x) = \sinh \theta x, \quad (\Gamma tg_s)(x) = \frac{1 - 2\nu}{2} x \sinh \theta x + B \cosh \theta x, \quad (17)\]

and

\[(\Gamma t^2 g_s)(x) = \frac{(1 - 2\nu)(3 - 2\nu)}{8} x^2 \sinh \theta x + x \cosh \theta x \left( \frac{1 - 2\nu}{2} B - \frac{1 - 4\nu^2}{8\theta} \right) + D \sinh \theta x. \quad (18)\]

Using (10) one gets

\[(\Gamma [(1 - t^2)g_c])'(x) = (\Gamma [(1 - t^2)g_c])(x). \quad (19)\]

From the above relations it follows that

\[ (\Gamma [(1 - t^2)g_c])'(x) = -\frac{(1 - 2\nu)(3 - 2\nu)}{8} [\theta x^2 \sinh \theta x + 2x \cosh \theta x] - \left( \frac{1 - 2\nu}{2} A - \frac{1 - 4\nu^2}{8\theta} \right) [\theta x \cosh \theta x + \sinh \theta x] + (1 - C) \theta \sinh \theta x. \quad (20)\]

Expressing the right-hand side through $(\Gamma t^2 g_s)$, $(\Gamma tg_c)$ and $(\Gamma g_s)$ one obtains

\[ (\Gamma [(1 - t^2)g_c])'(x) = -\theta (\Gamma t^2 g_s)(x) + \left( \theta (B - A) - \frac{3 - 2\nu}{2} \right) (\Gamma tg_c)(x) + \rho_1 (\Gamma g_s)(x) \quad (21)\]

where $\rho_1$ is a certain combination of constants $A$, $B$, and $C$.

As the solution of (11) is unique, the last equation implies that $g_c$ and $g_s$ have to obey the following ODE

\[ (1 - t^2)g_c'(t) = (\nu + \frac{1}{2} - \rho)tg_c(t) + (\rho_1 - \theta t^2)g_s(t) \quad (22)\]

with $\rho = (A - B)\theta + 2$.

Repeating these calculations for $g_s$ gives another equation

\[ (1 - t^2)g_s'(t) = (\nu + \frac{1}{2} + \rho)tg_s(t) + (\rho_2 - \theta t^2)g_c(t). \quad (23)\]

Imposing the condition that near the end $t = 1$ functions $g_c(t)$ and $g_s(t)$ have the prescribed singularities (cf. (11))

\[ g_c(t) \to \frac{k_c}{(1 - t)^{\nu + 1/2}}, \quad g_s(t) \to \frac{k_c \eta}{(1 - t)^{\nu + 1/2}} \quad (24)\]

where $\eta$ is determined from the limit

\[ \eta = \frac{k_s}{k_c} = \lim_{t \to 1} \frac{g_s(t)}{g_c(t)} \quad (25)\]

one fixes constants $\rho_1$ and $\rho_2$. 
Finally, we conclude that for $|\nu| < 1/2$ functions $g_c(t)$ and $g_s(t)$ obey the system of ODE

$$
\frac{\partial}{\partial t} \begin{pmatrix} g_c \\ g_s \end{pmatrix} = M \begin{pmatrix} g_c \\ g_s \end{pmatrix},
$$

with the following $2 \times 2$ matrix $M$

$$
M = \begin{pmatrix} 0 & \theta \\ \theta & 0 \end{pmatrix} + \frac{1}{1-t^2} \begin{pmatrix} t(\nu + 1/2 - \rho) & \frac{1}{\eta}(\nu + 1/2 + \rho) \\ \eta(\nu + 1/2 - \rho) & t(\nu + 1/2 + \rho) \end{pmatrix}.
$$

When $\nu = 0$ these equations coincide with the ones in [5].

For the further use we rewrite the system (26) in the form

$$
\frac{\partial}{\partial t} \begin{pmatrix} g_c - t\eta g_s \\ g_s - \eta t g_c \end{pmatrix} = -\frac{\theta t}{\eta} g_c + \left(\frac{\nu - \frac{1}{2} + \rho}{\eta} + \theta\right) g_s,
$$

$$
\frac{\partial}{\partial t} \begin{pmatrix} g_s - \eta t g_c \end{pmatrix} = -\theta t\eta g_s + \left(\eta(\nu - \frac{1}{2} - \rho) + \theta\right) g_c.
$$

The terms in the square brackets are zero when $t = \pm 1$ and this system can be obtained directly by using (10).

3. Second system of equations

To find constants $\rho$ and $\eta$ we use scaling arguments similar but different to the ones discussed in [6].

Functions $g_c$ and $g_s$ in (3) depend on $t$ and $\theta$, $g_{c,s} = g_{c,s}(t, \theta)$. We are interesting in finding equations governing the evolution of these function with changing $\theta$.

Consider instead of system (3) a more general system of equations

$$
\Gamma G_c \equiv \int_{L_1}^{L_2} |x - t|^\nu K_\nu(k|x - t|)G_c(t)dt = \cosh \left[k(x - \frac{1}{2}(L_1 + L_2))\right],
$$

$$
\Gamma G_s \equiv \int_{L_1}^{L_2} |x - t|^\nu K_\nu(k|x - t|)G_s(t)dt = \sinh \left[k(x - \frac{1}{2}(L_1 + L_2))\right].
$$

Changing the variable

$$
t = \frac{1}{2}(L_1 + L_2) + \frac{1}{2}(L_2 - L_1)y
$$

together with the similar change of $x$ it is straightforward to check that functions $G_c(y)$ and $G_s(y)$ are expressed through $g_c(t)$ and $g_s(t)$ defined in (3) as follows

$$
G_{c,s}(y) = \left(\frac{2}{L_2 - L_1}\right)^{\nu+1} g_{c,s}(z, \theta)
$$

where

$$
z = \frac{2}{L_2 - L_1}y - \frac{L_2 + L_1}{L_2 - L_1}, \quad \theta = \frac{1}{2}k(L_2 - L_1).
$$

Consider two functions

$$
\Psi_1(y) = G_s(y) + \eta G_c(y), \quad \Psi_2(y) = G_s(y) - \eta G_c(y)
$$
where $\eta$ is the same as in (23). By construction $\Psi_1(L_1) = 0$ and $\Psi_2(L_2) = 0$.

From (29) it follows that

$$\Gamma\Psi_1,2 = \Gamma G_s \pm \eta \Gamma G_c = \sinh \left( k(x - \frac{1}{2}(L_1 + L_2)) \right) \pm \eta \cosh \left( k(x - \frac{1}{2}(L_1 + L_2)) \right).$$  \hspace{1cm} (34)

As $\Psi_i(L_i) = 0$, the differentiation over $L_i$ of these equations gives

$$\frac{\partial}{\partial L_i}(\Gamma \Psi_i) = \Gamma \left( \frac{\partial}{\partial L_i} \Psi_i \right), \hspace{1cm} i = 1, 2.$$  \hspace{1cm} (35)

Using the uniqueness of the solutions, after simple algebra we obtain

$$\frac{\partial G_s}{\partial L_1} + \eta \frac{\partial G_c}{\partial L_1} = - \frac{\theta}{L_2 - L_1} (G_c + \eta G_s),$$
$$\frac{\partial G_s}{\partial L_2} - \eta \frac{\partial G_c}{\partial L_2} = - \frac{\theta}{L_2 - L_1} (G_c - \eta G_s).$$  \hspace{1cm} (36)

Performing the calculations one finds

$$\frac{\partial G_{c,s}}{\partial L_i} = \frac{(-1)^{i+1} (2L_2 - L_1)}{2L_2 - L_1} \nu^{i+1} \left( (1 + \nu)g_{c,s} + (z + (-1)^i) \frac{\partial g_{c,s}}{\partial z} - \theta \frac{\partial g_{c,s}}{\partial \theta} \right),$$  \hspace{1cm} (37)

where $i = 1$ for $G_c$ and $i = 2$ for $G_s$.

Combining all terms together one obtains that (36) take the the form

$$\theta \eta \frac{\partial g_c}{\partial \theta} = - \left( \frac{\partial g_s}{\partial z} - \eta z \frac{\partial g_c}{\partial z} \right) + (\theta + \eta(1 + \nu))g_c,$$
$$\theta \frac{\partial g_s}{\partial \theta} = - \left( z \frac{\partial g_s}{\partial z} - \eta \frac{\partial g_c}{\partial z} \right) + (\theta \eta + (1 + \nu))g_s.$$  \hspace{1cm} (38)

Using (28) we conclude that functions $g_{c,s}(t, \theta)$ obey the following system of equations

$$\frac{\partial}{\partial \theta} \begin{pmatrix} g_c \\ g_s \end{pmatrix} = N \begin{pmatrix} g_c \\ g_s \end{pmatrix}$$  \hspace{1cm} (39)

where matrix $N$ has the form

$$N = \begin{pmatrix} \frac{1}{2} + \rho & t \\ \theta & \frac{1}{2} - \rho \end{pmatrix}.$$  \hspace{1cm} (40)

The condition of compatibility of systems of equations (27) and (39) gives the equations of zero curvature for matrices $N$ and $M$

$$\frac{\partial}{\partial t} N - \frac{\partial}{\partial \theta} M = MN - NM.$$  \hspace{1cm} (41)

Direct calculations prove that this equation will be valid provided $\eta = \eta(\theta)$ and $\rho = \rho(\theta)$ fulfil the equations

$$\rho = \frac{\theta}{2\eta}(1 - \eta' - \eta^2),$$  \hspace{1cm} (42)
and
\[ \rho' = \frac{\nu + 1/2 + \rho}{\eta} - (\nu + 1/2 - \rho)\eta. \] (43)

Substituting here the previous equation one finds that \( \eta \) has to obey equation
\[ \frac{d^2\eta}{d\theta^2} = \eta^{-1} \left( \frac{d\eta}{d\theta} \right)^2 - \theta \frac{d\eta}{d\theta} - \frac{2\nu(1 - \eta^2)}{\theta} + \eta^3 - \frac{1}{\eta}. \] (44)

This equation is a particular form of Painlevé III equation which has been discussed in [10].

From the results of Appendix A and Appendix B it follows that functions \( g_c(\cos\gamma) \) and \( g_s(\cos\gamma) \) can be written as the following series of the spheroidal functions
\[ g_c(\cos\gamma) = \frac{1}{(\sin\gamma)^{2\nu+1}} \sum_{m=0}^{\infty} \mu_{2m}\tilde{X}_{2m}(0) Y_{2m}(\gamma), \] (45)
\[ g_s(\cos\gamma) = \frac{1}{(\sin\gamma)^{2\nu+1}} \sum_{m=0}^{\infty} \mu_{2m+1}\tilde{X}_{2m+1}(0) Y_{2m+1}(\gamma), \] (46)
where \( Y_m(\cos\gamma) \) are defined in (B.1), \( X_m(\xi) \) in (B.18), and \( \mu_n \) in (A.24).

Function \( \eta \) in (25) which is a solution of the Painlevé III equation is given as the ratio of the above series
\[ \eta = \frac{\sum_{m=0}^{\infty} \mu_{2m+1}\tilde{X}_{2m+1}(0) Y_{2m+1}(0)}{\sum_{m=0}^{\infty} \mu_{2m}\tilde{X}_{2m}(0) Y_{2m}(0)}. \] (47)

4. Limiting behaviour

In order to use the equations derived in the previous Sections it is necessary to know the behaviour of \( g_c(t) \) and \( g_s(t) \) defined in (8) in the limit of small \( \theta \) and (or) large \( \theta \).

From (5) it follows that at small \( \theta \)
\[ K(w) \xrightarrow{\theta \to 0} \theta^{-\nu} \frac{\Gamma(\nu)}{2^{1-\nu}} + w^{2\nu} \theta^\nu \frac{\Gamma(-\nu)}{2^{1+\nu}}. \] (48)

Therefore, to find the necessary solutions of (8) when \( \theta \to 0 \) it is necessary first to solve the equation
\[ \int_{-1}^{1} |x-t|^{2\nu} g(t) dt = f(x) \] (49)
when function \( f(x) \) equals 1 or \( x \).

Though the general solution of such equation is known (see e.g. [12]), solutions with \( f(x) = 1 \) and \( f(x) = x \) can easily be obtained by the direct application of Latta’s method [5]. After a simple algebra one finds that the solutions of equations
\[ \int_{-1}^{1} |x-t|^{2\nu} g_0(t) dt = 1, \quad \int_{-1}^{1} |x-t|^{2\nu} g_1(t) dt = x \] (50)
are
\[ g_0(t) = \frac{\cos(\pi\nu)}{\pi(1-t^2)^{\nu+1/2}}, \quad g_1(t) = -\frac{\cos(\pi\nu)t}{2\pi\nu(1-t^2)^{\nu+1/2}}. \] (51)
Painlevé solution of an integral equation

From (48) we obtain that

\[ g_c(t) \xrightarrow{\theta \to 0} \mu_c g_0(t), \quad g_s(t) \xrightarrow{\theta \to 0} \mu_s g_1(t) \]  

(52)

where constants \( \mu_c \) and \( \mu_s \) are determined from the conditions

\[ \mu_c \left( \theta \nu \Gamma(\nu) \frac{\cos(\pi \nu)}{2^{1+\nu}} \right) = 1, \quad \mu_s \theta^\nu \Gamma(-\nu) = \theta. \]  

(53)

From these relations it follows that

\[ \eta(\theta) \xrightarrow{\theta \to 0} -\frac{\mu_s \theta}{2 \nu \mu_c} = -\theta^{1-2\nu} \frac{\cos(\pi \nu) \Gamma(1/2 - \nu) \Gamma(\nu)}{\sqrt{\pi} 2^{1-2\nu} \nu \Gamma(1-\nu) \Gamma(-\nu)} - \frac{\theta}{2\nu}. \]  

(54)

Using standard formulae for the \( \Gamma \)-function

\[ \Gamma(2\nu) = \frac{2^{2\nu-1}}{\sqrt{\pi}} \Gamma(\nu) \Gamma(\nu + 1/2), \quad \Gamma(1/2 + \nu) \Gamma(1/2 - \nu) = \frac{\pi}{\cos(\pi \nu)}, \]  

(55)

one gets that the limiting behaviour of \( \eta(\theta) \) at small \( \theta \) is

\[ \eta(\theta) \xrightarrow{\theta \to 0} B(2\theta)^{-1-2\nu} \frac{\theta}{2\nu} = \begin{cases} B(2\theta)^{1-2\nu}, & 0 < \nu < 1/2 \\ -\theta/(2\nu), & -1/2 < \nu < 0 \end{cases} \]  

(56)

where

\[ B = 2^{-3(1-2\nu)} \frac{\Gamma^2(\nu)}{\Gamma^2(1-\nu) \Gamma(2\nu)}. \]  

(57)

To find the behaviour of solutions when \( \theta \to \infty \) it is convenient to consider instead of functions \( g_{c,s} \) (8) a solution \( g_- (v) \) corresponding to the integral equation

\[ \int_{-1}^{1} |u - v|^{\nu} K_\nu(\theta |u - v|) g_-(v) dv = e^{-\theta u}. \]  

(58)

To find asymptotic behaviour of \( g_- \) for large \( \theta \) we first consider the equation

\[ \int_0^\infty |u - v|^{\nu} K_\nu(|u - v|) g_0(v) dv = e^{-u}. \]  

(59)

Its solution can be calculated either by the Wiener-Hopf method [13] using known Fourier transform of the kernel

\[ \int_{-\infty}^{\infty} e^{ipx} K_\nu(\theta x) x^{\nu} dx = \frac{(2\theta)^\nu \sqrt{\pi} \Gamma(\nu + 1/2)}{(p^2 + \theta^2)^{\nu+1/2}} \]  

(60)

or by expansion formulae analogous to the ones described in Appendix A but for half-line integration [15]

\[ n! \int_0^\infty |x - t|^{\nu} K_\nu \left( \frac{1}{2} |x - t| \right) t^{-\nu-1/2} e^{-t/2} L_n^{-\nu-1/2} (t) dt = \sqrt{\pi} \Gamma(\nu + 1/2) \Gamma(n + 1/2 - \nu) e^{-x/2} L_n^{-\nu-1/2} (x) \]  

(61)
where $L_n^\lambda(x)$ with $n = 0, 1, \ldots$ are the Laguerre polynomials.

One gets

$$g_0(v) = C_\nu v^{-\nu-1/2}e^{-v}, \quad C_\nu = \frac{\sqrt{2}}{\pi^{3/2}} \cos \pi \nu. \quad (62)$$

Using this solution it is easy to show that the dominant approximation for the solution of $\text{(58)}$ when $\theta \to \infty$ has the form

$$g_-^{(0)}(t) = C_\nu \sqrt{\theta}(1 + t)^{-\nu-1/2}e^{-\theta}. \quad (63)$$

Straightforward transformations give

$$\int_{-1}^{1} |x - t|^{\nu} K_\nu(\theta|x - t|)g_-^{(0)}(t)dt = F_1(x) - F_2(x) \quad (64)$$

where

$$F_1(x) = \int_{-1}^{\infty} |x - t|^{\nu} K_\nu(\theta|x - t|)g_-^{(0)}(t)dt, \quad F_2(x) = \int_{1}^{\infty} |x - t|^{\nu} K_\nu(\theta|x - t|)g_-^{(0)}(t)dt. \quad (65)$$

Changing the variable in the first integral as $t = -1 + v/\theta$ and using $(59)$ leads to

$$F_1(x) = e^{-\theta x}. \quad (66)$$

In the integral for $F_2(x)$ it is convenient to put $t = 1 + s/\theta$. It this way one obtains

$$F_2(x) = \theta^{-\nu-1/2}C_\nu \int_{0}^{\infty} \left(2 + \frac{s}{\theta}\right)^{-\nu-1/2}(s + \theta(1 - x))^{\nu} K_\nu(s + \theta(1 - x))e^{-\theta s}ds. \quad (67)$$

When $\theta$ is large one can drop the term $s/\theta$ in the first bracket and use the asymptotic form of the $K_\nu$ function $(41)$

$$F_2(x) \xrightarrow{\theta \to \infty} \theta^{-\nu-1/2}2^{-\nu-1}\sqrt{\pi e^{-2\theta x}}C_\nu \int_{0}^{\infty} (s + \theta(1 - x))^{\nu-1/2}e^{-2s}ds. \quad (68)$$

This formula means that close to right-hand side, $x = 1$, the additional contribution related with the integration in finite limits is

$$F_2(x) \approx \theta^{-\nu-1/2}2^{-\nu-1}\sqrt{\pi e^{-2\theta x}}C_\nu \int_{0}^{\infty} s^{-\nu-1/2}e^{-2s}ds = e^{\theta x}\delta \quad (69)$$

where

$$\delta = \frac{1}{2\pi}\theta^{-\nu-1/2}2^{-2\nu}\cos(\pi \nu)e^{-2\theta} \Gamma(\nu + 1/2). \quad (70)$$

Using $(58)$ it is obvious that to cancel contribution $F_2(x)$ it is necessary to modify the approximation $(63)$ as follows

$$g_-^{(0)}(t) \xrightarrow{\theta \to \infty} C_\nu \sqrt{\theta}\left[(1 + t)^{-\nu-1/2}e^{-\theta} + \delta(1 - t)^{-\nu-1/2}e^{\theta}\right]. \quad (71)$$

This function consists of two terms. The first dominates close to $t = -1$ and the second near $t = 1$. According to $(25)$ function $\eta(\theta)$ is determined from the limit

$$\eta(\theta) = \lim_{t \to -1} \frac{g_-^{(0)}(-t) - g_-^{(0)}(t)}{g_-^{(0)}(-t) + g_-^{(0)}(t)}. \quad (72)$$

Using $(71)$ we find that

$$\eta(\theta) \xrightarrow{\theta \to \infty} 1 - \frac{\cos(\pi \nu)}{\pi} \Gamma(\nu + 1/2)2^{-2\nu}\theta^{-\nu-1/2}e^{-2\theta}. \quad (73)$$
5. Embedding formulae

In the previous Sections the integral equation (1) has been transformed into two systems of ODE (26), (27) and (39), (40) but only for very special right-hand sides of this equation, \( f(x) = \cosh(\theta x) \) and \( f(x) = \sinh(\theta x) \) (cf. (8)). Nevertheless, the knowledge of these two special solutions permits to find solutions of (1) for more general cases [7, [8].

Let us consider the equation of the form

\[
(\Gamma g)(x) = e^{-\theta zx}
\]

with the same kernel as in (2). To find its solution, \( g(t) \), it is convenient to define symmetric and antisymmetric combinations of \( g_c, s \)

\[
g_\pm(t) = g_c(t) \pm g_s(t)
\]

We look for solution of (74) in the form

\[
\Psi(t) = g(t) + a_+g_+(t) + a_-g_-(t)
\]

where \( a_+ \) and \( a_- \) are two constants independent on \( t \) which have to be determined from two conditions

\[
\lim_{t \to \pm 1} \Psi(t) = 0
\]

The explicit form of these constants will be presented later (see (89)).

Assuming that (77) is fulfilled, one concludes as in Section 2 that

\[
(\Gamma \Psi(x))' = (\Gamma \Psi')(x)
\]

The right-hand side of this equation is calculated from the definition of \( \Psi \) and

\[
(\Gamma \Psi(x))' = -\theta z e^{-\theta zx} + \theta a_+ e^{\theta x} - \theta a_- e^{-\theta x} = (\Gamma[-z\theta g + a_+\theta g_+ - a_-\theta g_-])(x)
\]

Due to the uniqueness of the solution, \( \Psi(t) \) obeys the equation

\[
\Psi'(t) = -z\theta \left( \Psi(t) - a_+g_+(t) - a_-g_-(t) \right) + a_+\theta g_+(t) + a_-\theta g_-(t)
\]

which is equivalent to

\[
\theta^{-1}\Psi'(t) + z\Psi(t) = (z + 1)a_+g_+(t) + (z - 1)a_-g_-(t)
\]

whose solution is straightforward if constants \( a_\pm \) are known.

To find them one can proceed as follows [8]. Let us calculate the following quantities

\[
(g_\pm \Gamma \Psi) \equiv \int_{-1}^{1} \int_{-1}^{1} g_\pm(x)K(x-t)\Psi(t)dt\,dx
\]
Painlevé solution of an integral equation

by two different methods, the first by applying the operator $\Gamma$ on $g_{\pm}$ and the second by applying it on $\Psi$. In such a manner one gets

$$\int_{-1}^{1} \Psi(t)e^{\pm \theta t} dt = \int_{-1}^{1} g_{\pm}(t)\left(e^{-z \theta t} + a_{+}e^{\theta t} + a_{-}e^{-\theta t}\right)dt .$$

(83)

Introduce the Laplace transform of functions $g_{c,s}$

$$\hat{G}_{c}(p) = \int_{-1}^{1} g_{c}(t)e^{\theta pt} dt , \quad \hat{G}_{s}(p) = \int_{-1}^{1} g_{s}(t)e^{\theta pt} dt .$$

(84)

Due to the symmetry properties of $g_{c,s}$, $\hat{G}_{c}(-p) = \hat{G}_{c}(p)$ and $\hat{G}_{s}(-p) = -\hat{G}_{s}(p)$.

Using (84) we obtain

$$\int_{-1}^{1} \Psi(t)e^{\theta t} dt = G(-z) + a_{+}G(1) + a_{-}G(-1) ,$$

(85)

$$\int_{-1}^{1} \Psi(t)e^{-\theta t} dt = G(z) + a_{+}G(-1) + a_{-}G(1)$$

(86)

where $G(p) = \hat{G}_{c}(p) + \hat{G}_{s}(p)$.

On the other hand, multiplying (81) by $e^{\pm \theta t}$, integrating the results from $-1$ to $1$, and taking into account that $\Psi(\pm 1) = 0$ one finds

$$(z - 1) \int_{-1}^{1} e^{\theta t}\Psi(t)dt = (z + 1)a_{+}G(1) + (z - 1)a_{-}G(-1) ,$$

(87)

$$(z + 1) \int_{-1}^{1} e^{-\theta t}\Psi(t)dt = (z + 1)a_{+}G(-1) + (z - 1)a_{-}G(1) .$$

(88)

These and previous equations permits to calculate constants $a_{\pm}$

$$a_{\pm} = -\frac{(1 \mp z)G(\mp z)}{2G(1)} .$$

(89)

Combining the above formulae one finds that (81) takes the form

$$\theta^{-1}\Psi'(t) + z\Psi(t) = \frac{z^{2} - 1}{G(1)} \left[\hat{G}_{c}(z)g_{s}(t) - \hat{G}_{s}(z)g_{c}(t)\right]$$

(90)

whose solution obeying $\Psi(\pm 1) = 0$ is

$$\Psi(t) = \frac{(z^{2} - 1)\theta}{G(1)} e^{-z\theta t}\left[\hat{G}_{c}(z) \int_{-1}^{t} g_{s}(y)e^{z\theta y}dy - \hat{G}_{s}(z) \int_{-1}^{t} g_{s}(y)e^{z\theta y}dy\right] .$$

(91)

The above formulae relate the general plane-wave solution (74) to two special cases corresponding to $z = \pm 1$. Such formulae are called embedding formulae in the theory of diffraction and can be derived in more general settings (see e.g. [14] and references therein).
6. Positivity relations

Equation (91) represents the solution of (74). As for usual diffraction problems it is physically clear (and can be proved e.g. by using the series expansions as in Appendix A) that such solution exist for all \( \theta > 0 \) and any \( z \) but (91) contains \( G(1) \) in the numerator and in order to the solution remains finite it is necessary that this quantity is always non-zero.

By the construction \( G(1) \) is the Laplace transform of the sum \( g_c + g_s \)

\[
G(1) = \int_{-1}^{1} (g_c(t) + g_s(t))e^{\theta t}dt = \int_{-1}^{1} g_c(t) \cosh(\theta t)dt + \int_{-1}^{1} g_s(t) \sinh(\theta t)dt .
\]

By definition, \( g_c(t) \) and \( g_s(t) \) are solutions of (8) thus

\[
cosh(\theta x) = (\Gamma g_c)(x), \quad \sinh(\theta x) = (\Gamma g_s)(x)
\]

and

\[
G(1) = \int_{-1}^{1} dt \int_{-1}^{1} g_c(t)K(|x-t|)g_c(x)dx + \int_{-1}^{1} dt \int_{-1}^{1} g_s(t)K(|x-t|)g_s(x)dx
\]

with the kernel \( K(w) \) defined in (2). An important property of such kernel is that its Fourier transform, \( \hat{K}(p) \), presented (60) is strictly positive for all \( p \) and \( \nu > -1/2 \). It means that function \( K(w) \) is a positive definite function and the double integral

\[
\int_{-1}^{1} dt \int_{-1}^{1} f(t)K(|x-t|)f(x)dx \equiv \frac{1}{2\pi} \int_{-\infty}^{\infty} \left| \int_{-1}^{1} f(t)e^{ip\theta}dt \right|^2 \hat{K}(p)dp
\]

is positive for any function \( f(x) \). Therefore for all \( \theta > 0 \)

\[
G(1) > 0
\]

and the solution (91) is finite for all \( z \).

The same positivity condition permits also to establish the positivity and finiteness of \( \eta(\theta) \). Formally, this function is defined as the limit when \( t \to 1 \) of the ratio of two solutions (25) and it is not evident that it remains finite for all \( \theta > 0 \).

Let us define two functions

\[
\hat{F}_c(p) = \int_{-1}^{1} tg_c(t)e^{\eta \theta t}dt , \quad \hat{F}_s(p) = \int_{-1}^{1} tg_s(t)e^{\eta \theta t}dt
\]

which differ from (84) by factor \( t \) in the integrand.

Multiplying (28) by \( e^{\eta \theta t} \) and integrating the both parts over the interval \([-1, 1]\) one finds

\[
\begin{align*}
\left[ \frac{\nu - 1/2 - \rho}{\theta} + \frac{1}{\eta} \right] \hat{G}_c(z) + \frac{z}{\eta} \hat{G}_s(z) = z\hat{F}_c(z) + \hat{F}_s(z) , \\
\left[ \frac{\nu - 1/2 + \rho}{\theta} + \eta \right] \hat{G}_s(z) + z\eta \hat{G}_c(z) = \hat{F}_c(z) + z\hat{F}_s(z) .
\end{align*}
\]
From (39) and (40) it follows that
\[
\begin{align*}
\frac{\partial}{\partial \theta} \hat{G}_c(z) - \frac{1}{2} + \frac{\rho}{\theta} \hat{G}_c(z) &= \hat{F}_c(z) + z \hat{F}_c(z), \\
\frac{\partial}{\partial \theta} \hat{G}_s(z) - \frac{1}{2} - \frac{\rho}{\theta} \hat{G}_s(z) &= \hat{F}_c(z) + z \hat{F}_s(z).
\end{align*}
\] (99)

Combining these relations one concludes that
\[
\begin{align*}
\frac{\partial}{\partial \theta} \hat{G}_c(z) - \left[ \frac{\nu}{\theta} + \frac{1}{\eta} \right] \hat{G}_c(z) &= \frac{z}{\eta} \hat{G}_s(z), \\
\frac{\partial}{\partial \theta} \hat{G}_s(z) - \left[ \frac{\nu}{\theta} + \eta \right] \hat{G}_s(z) &= z \eta \hat{G}_c(z).
\end{align*}
\] (100)

Put in the last expressions \( z = 1 \). Then \( G(1) = \hat{G}_c(1) + \hat{G}_s(1) \) obeys the equation
\[
\frac{\partial}{\partial \theta} G(1) = \left[ \frac{\nu}{\theta} + \eta + \frac{1}{\eta} \right] G(1) \] (101)
whose solution is
\[
G(1) = C'(\nu) \theta^\nu \exp \int_0^\theta (\eta(\theta') + \eta^{-1}(\theta')) d\theta'
\] (102)
where \( C'(\nu) \) is a constant.

Using (24), (39), and (40) with \( t = 1 \) one concludes that
\[
\frac{\partial}{\partial \theta} k_c = \frac{1}{2} + \frac{\rho}{\theta} k_c + k_c \eta.
\] (103)
Solving it and using (42) we finds
\[
k_c^2 = C''(\nu) \frac{\theta}{\eta} \exp \int_0^\theta (\eta(\theta') + \eta^{-1}(\theta')) d\theta'
\] (104)
with another constant \( C''(\nu) \).

Comparison of this expression with (102) proves that
\[
\eta k_c^2 = C(\nu) \theta^{1-\nu} G(1).
\] (105)
To find the constant of proportionality, \( C(\nu) \), we compare the both sides of this equation when \( \theta \to 0 \).

From Section 4 it follows that for \( |\nu| < 1/2 \) and \( \theta \to 0 \) the dominant contribution to \( G(1) \) is due to \( \hat{G}_c(1) \) and it is straightforward to check that
\[
C(\nu) = \frac{\cos \pi \nu}{2\nu+1+\pi^2} \Gamma(1/2 - \nu).
\] (106)
For \( |\nu| < 1/2 \), \( C(\nu) > 0 \) and due to the positivity of \( G(1) \) it follows from (105) that \( \eta > 0 \) for all positive \( \theta > 0 \). As the only possible moving singularities of \( \eta \) are poles this reasoning proves that \( \eta \) is bounded for all \( \theta > 0 \) (the behaviour of \( \eta \) at large \( \theta \) is fixed by (73)).
The list of solutions of the Painlevé III equation \((44)\) which remain bounded as \(\theta \to \infty\) along the real axis has been presented in [10]. Such solutions form one parameter family parametrized by parameter \(\lambda\) which determined the large \(\theta\) behaviour of solutions
\[
\eta(\theta) \xrightarrow{\theta \to \infty} 1 - \lambda \Gamma(\nu + 1/2)2^{-2\nu} \theta^{-\nu-1/2} e^{-2\theta} .
\] (107)

Bounded solutions are characterized by the following behaviour at small \(\theta\)
\[
\eta(\theta) \xrightarrow{\theta \to 0} (2\theta)^\sigma B + (2\theta)B_1 + (2\theta)^{1+2\sigma} B_2 + (2\theta)^{2-\sigma} B_3 + O(\theta^{2+\sigma})
\] (108)
where \(\sigma\) (restricted by inequalities \(-1 < \text{Re} \sigma < 1\)) is related with \(\lambda\) as follows
\[
\sigma = \frac{2}{\pi} \arcsin(\pi \lambda) .
\] (109)
and coefficients \(B_j\) are
\[
B_1 = -\frac{\nu}{(1-\sigma)^2}, \quad B_2 = B^2 \frac{\nu}{(1+\sigma)^2}, \quad B_3 = \frac{1}{16B(1-\sigma)^4}(4\nu^2 - (1-\sigma)^2)
\] (110)
with \(B = B(\sigma, \nu)\) being a function of \(\sigma\) and \(\nu\)
\[
B(\sigma, \nu) = 2^{-3\sigma} \frac{\Gamma^2(((1-\sigma)/2)\Gamma((1+\sigma)/2 + \nu)}{\Gamma^2((1+\sigma)/2)\Gamma((1-\sigma)/2 + \nu)} .
\] (111)
When \(0 < \nu < 1/2\) the solution of the integral equation \((\Pi)\) discussed above corresponds to a particular case of general theory in [10] with \(\sigma = 1 - 2\nu\) (cf. \((57)\), \((111)\), and \((73)\)). It seems that the case when \(-1/2 < \nu < 0\) is missed from the analysis of [10] as \(1 < \sigma = 1 - 2\nu < 2\). For such choice of \(\sigma\) the term \(B_3\) in \((110)\) is identically zero and the asymptotics \((56)\) represents the two leading terms when \(\theta \to 0\). Though in this case the dominant behaviour at small \(\theta\) is linear in \(\theta\), \(\eta \to -\theta/(2\nu)\), its asymptotics at large \(\theta\) is given by the same formula \((107)\) but with value of \(\lambda\) obtained by the inversion of \((109)\) (see \((73)\))
\[
\lambda = \frac{\cos(\pi \nu)}{\pi} .
\] (112)

7. Conclusion

We demonstrate that special solutions of the integral equation \((\Pi)\) can be obtained from ordinary differential equations \((26), (27)\) or \((39), (40)\) with entering constants calculated using the Painlevé III equation \((44)\) with known asymptotics at small and large arguments. Our finding generalizes the results obtained in [6] for the special case \(\nu = 0\). An interesting consequence of our investigation is the expression \((47)\) for a solution of the Painlevé III equation with asymptotics given by \((56)\) and \((73)\) as the ratio of two infinite series of spheroidal functions with known coefficients. The positive-definiteness of the kernel forces this Painlevé III solution to be bounded for all positive arguments thus giving another proof of connection formulae for the Painlevé III equation [10] in a special case.
Painlevé solution of an integral equation

Acknowledgments

One of the author (EB) is greatly indebted to A. Its for pointing out the important reference [6].

Appendix A. Series solution of the integral equation

Let $\mu_m$ and $Y_m(\gamma)$ be generalized eigenvalues and eigenfunctions of operator (2)

$$\mu_m \int_0^\pi (\sin \gamma)^{-2\nu} K(|\cos \beta - \cos \gamma|) Y_m(\gamma) d\gamma = Y_m(\beta) . \quad (A.1)$$

As the symmetrized version of the kernel has the form

$$\tilde{K}(\beta, \gamma) = (\sin \beta)^{-\nu} K(|\cos \beta - \cos \gamma|)(\sin \gamma)^{-\nu} \quad (A.2)$$

eigenfunctions $Y_m(\gamma)$ form an orthogonal system of functions

$$\int_0^\pi (\sin \gamma)^{-2\nu} Y_m(\gamma) Y_n(\gamma) d\gamma = N_m \delta_{mn} \quad (A.3)$$

where $N_m$ is the normalization constant.

If a function $f(x)$ is expanded into a series of functions $Y_m(\gamma)$

$$f(\cos \gamma) = \sum_m a_m Y_m(\gamma) \quad (A.4)$$

then the formal solution of the integral equation (1) is

$$g(\cos \gamma) = (\sin \gamma)^{-2\nu-1} \sum_{m=1}^\infty \mu_m a_m Y_m(\gamma) . \quad (A.5)$$

To find explicitly eigenvalues and eigenfunctions of (A.1) it was noted in (1) that the function

$$K(\sqrt{x^2 + y^2})$$

plays the role of the Green function of the equation

$$\left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} - \frac{2\nu}{y} \frac{\partial}{\partial y} - \theta^2 \right) \Psi(x, y) = 0 . \quad (A.6)$$

Therefore the function

$$\Psi^{(\text{ref})}(x, y) = \int_{-1}^1 g(t) K(\sqrt{(t - x)^2 + y^2}) dt \quad (A.7)$$

is a uni-valued solution of (A.6) in all points of the $(x, y)$-plane except the strip $[-1, 1]$ which exponentially decays at large distances

$$\Psi^{(\text{ref})}(r \cos \phi, r \sin \phi) \underset{r \to \infty}{\longrightarrow} \sqrt{\frac{2}{\theta \pi}} r^{-1/2} e^{-\theta r} \int_{-1}^1 g(t) e^{\theta t \cos \phi} dt . \quad (A.8)$$
Consider a Dirichlet-type problem of finding the solution of (A.6) in the form
\[ \Psi(x, y) = \Psi^{(\text{inc})}(x, y) + \Psi^{(\text{ref})}(x, y) \]  
where \( \Psi^{(\text{inc})}(x, y) \) also obeys (A.6) and the total field \( \Psi(x, 0) \) is zero at the interval \([-1, 1]\)
\[ \Psi(x, 0) = 0, \quad -1 \leq x \leq 1 \]  
It means that unknown function \( g(t) \) obeys (1) with \( f(x) = -\Psi^{(\text{inc})}(x, 0) \).

Equation (A.6) permits the separation of variables in the elliptic coordinates
\[ x = \cosh \xi \cos \gamma, \quad y = \sinh \xi \sin \gamma \]  
It is plain that
\[ \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} = \frac{2}{\cosh 2\xi - \cos 2\gamma} \left( \frac{\partial^2}{\partial \xi^2} + \frac{\partial^2}{\partial \gamma^2} \right), \]  
and
\[ \frac{\partial}{\partial y} = \frac{2}{\cosh 2\xi - \cos 2\gamma} \left( \cosh \xi \sin \gamma \frac{\partial}{\partial \xi} + \sinh \xi \cos \gamma \frac{\partial}{\partial \gamma} \right). \]
If \( \Psi(x, y) = X(\xi)Y(\gamma) \) then \( Y(\gamma) \) and \( X(\xi) \) obey
\[ Y''_m - 2\nu \cot \gamma Y'_m - (\alpha_m - \frac{1}{2} \theta^2 \cos 2\gamma) Y_m = 0 \]  
and
\[ X''_m - 2\nu \coth \xi X'_m + (\alpha_m - \frac{1}{2} \theta^2 \cosh 2\xi) X_m = 0 \]  
The separation constant, \( \alpha_m \), is chosen to ensure the symmetry properties of solutions
\[ Y_m(-\gamma) = Y_m(\gamma), \quad Y_m^{(\gamma)} = Y_m(\gamma + \pi). \]  
The solution \( X_m(\xi) \) is fixed by its normalization at infinity
\[ X_m(\xi) \xrightarrow{\xi \to \infty} Ce^{\xi(\nu-1/2)} \exp \left( -\frac{\theta}{2} e^\xi \right) \]  
where \( C \) is a constant.

The above equations are particular cases of spheroidal equation [9]. \( Y_m(\gamma) \) is even periodic angular solution of (A.14) and \( X_m(\xi) \) is the radial solution of the modified equation (A.15) decreasing at the infinity. It is known that \( Y_m \) are orthogonal functions on interval \([0, \pi]\) as in (A.3) and they form a complete set in the space of even functions on this interval.

Therefore, the reflected uni-valued field in the \((x, y)\)-plane cut along the interval \([-1, 1]\), decaying at infinity (cf. (A.17)), and obeying (A.10) with \( f(x) \) as in (A.4) can be represented as a formal series
\[ \Psi^{(\text{ref})}(\xi, \gamma) = \sum_m a_m \frac{X_m(\xi)}{X_m(0)} Y_m(\gamma). \]
As for the usual Dirichlet problem the value of \( g(t) \) in (A.7) is related with the normal derivative of \( \Psi^{(\text{ref})} \) at the strip \([-1,1]\). At small \( w \)

\[
K_\nu(w) \xrightarrow{w \to 0} w^{-\nu} \frac{\Gamma(\nu)}{2^{1-\nu}} + w^{\nu} \frac{\Gamma(-\nu)}{2^{1+\nu}} .
\] (A.19)

As \( w = \sqrt{(x-t)^2 + y^2} \) and for \( \nu < 1/2 \)

\[
\lim_{y \to 0^+} \frac{y^{1-2\nu}}{(x^2 + y^2)^{1-\nu}} = \frac{\sqrt{\pi} \Gamma(1/2 - \nu)}{\Gamma(1-\nu)} \delta(x)(A.20)
\]

one gets that \( g(x) = -\frac{2^\nu \theta^{-\nu}}{\sqrt{\pi} \Gamma(1/2 - \nu)} \lim_{y \to 0} y^{-2\nu} \frac{\partial}{\partial y} \Psi^{(\text{ref})}(x,y) . \) (A.21)

The behaviour of the decaying solution \( X_m(\xi) \) at small \( \xi \) follows from (A.13)

\[
X_m(\xi) \xrightarrow{\xi \to 0} A_m + B_m \xi^{1+2\nu} .
\] (A.22)

For \( x \) in the strip \([-1,1]\) and small \( y, y = \xi \sin \gamma \). Therefore

\[
g(\cos \gamma) = -\frac{2^\nu (2\nu + 1) \theta^{-\nu}}{\sqrt{\pi} \Gamma(1/2 - \nu)} (\sin \gamma)^{-2\nu-1} \sum m a_m \frac{B_m}{A_m} Y_m(\gamma) . \] (A.23)

It means that eigenfunctions of operator (A.1) equal \( Y_m \) and the corresponding eigenvalues are

\[
\mu_m = -\frac{2^\nu \theta^{-\nu} (2\nu + 1) B_m}{\sqrt{\pi} \Gamma(1/2 - \nu) A_m} \] (A.24)

where \( A_m \) and \( B_m \) are determined from the dominant behaviour at small \( \xi \) of the decaying solution of the radial equation \( X_m(\xi) \) (A.22).

Appendix B. Spheroidal functions

A convenient method to find periodic functions \( Y_m(\gamma) \) is to expand them into a series of Gegenbauer’s polynomials \( \text{[9]} \)

\[
Y_m(\gamma) = \sum_{n \equiv m \mod 2} b_n C_n^{-\nu}(\cos \gamma) \] (B.1)

where the summation is performed over all non-negative integers of the same parity as \( m \).

Here \( C_n^\mu(x) \) are polynomial solutions of the equation

\[
(1 - x^2) y'' - (2\mu + 1) xy' + n(n + 2\mu) y = 0 \] (B.2)

and \( C_n^\mu(\cos \gamma) \) are solutions of

\[
y'' + 2\mu \cot \gamma y' + n(n + 2\mu) y = 0 . \] (B.3)
We impose the standard normalization [11]

\[ C_n^\mu(1) = \frac{\Gamma(n + 2\mu)}{n!\Gamma(2\mu)} \]  

so the orthogonality relation for Gegenbauer’s polynomials is

\[ \int_{-1}^{1} (1 - x^2)^{\mu-1/2}C_n^\mu(x)C_m^\mu(x)dx = \frac{2^{1-2\mu}\pi\Gamma(n + 2\mu)}{n![\Gamma(\mu)]^2(n + \mu)}. \]  

(B.5)

Notice that [11]

\[ \mu C_n^\mu(\cos \gamma) \xrightarrow{\mu \to 0} \frac{2}{n}\cos(n\gamma) \]  

(B.6)

so for \( \mu \to 0 \) series (B.1) can be transformed to series used for even Mathieu functions.

Using the recurrence relation for Gegenbauer polynomials [11]

\[ (n + 1)C_{n+1}^\mu(x) = 2(n + \mu)xC_n^\mu(x) - (n + 2\mu - 1)C_{n-1}^\mu(x) \]  

(B.7)

gives

\[ \cos 2\gamma C_n^{-\nu}(\cos \gamma) = A_n C_n^{-\nu}(\cos \gamma) + B_{n-2} C_{n-2}^{-\nu}(\cos \gamma) + D_{n+2} C_{n+2}^{-\nu}(\cos \gamma) \]  

(B.8)

where

\[ A_n = -\frac{\nu(1 + \nu)}{(n - \nu)^2 - 1}, \quad B_n = \frac{(n - 2\nu + 1)(n - 2\nu)}{2(n - \nu + 2)(n - \nu + 1)}, \quad D_n = \frac{(n - 1)n}{2(n - \nu - 2)(n - \nu - 1)} \]  

(B.9)

Substituting the formal series (B.1) into (A.14) leads to a three-diagonals matrix for the determination of \( b_n \) with fixed parity

\[ \left[ \frac{1}{2}\theta^2 A_n - n(n - 2\nu) \right] b_n + \frac{1}{2}\theta^2 B_n b_{n+2} + \frac{1}{2}\theta^2 D_n b_{n-2} = \alpha_m b_n. \]  

(B.10)

Eigenvalues of the above matrix determine separation constants \( \alpha_m \).

From (B.5) it follows that the normalization constant for this solution is

\[ N_m = \sum_{n \equiv m \mod 2} b_n^2 \frac{2^{1-2\nu}\pi\Gamma(n + 2\mu)}{n![\Gamma(\mu)]^2(n + \mu)}. \]  

(B.11)

The function \( e^{\theta x} \) is a solution of (A.6). Therefore it can be expanded in elliptic coordinates (A.11) as

\[ e^{\theta \cosh \xi \cos \gamma} = \sum_{m} Y_m(\gamma) \tilde{X}_m(\xi) \]  

(B.12)

where \( \tilde{X}_m(\xi) \) are certain solutions (to be discussed below) of the modified equation (A.15).

Using (A.3) one gets

\[ \tilde{X}_m(\xi) = \frac{1}{N_m} \int_{0}^{\pi} (\sin \gamma)^{-2\nu} e^{\theta \cosh \xi \cos \gamma} Y_m(\gamma) d\gamma. \]  

(B.13)
Due to the symmetry properties (A.16)

\[ \tilde{X}_{2m}(\xi) = \frac{1}{N_{2m}} \int_{0}^{\pi} (\sin \gamma)^{-2\nu} \cosh[\theta \cosh \xi \cos \gamma] Y_{2m}(\gamma) d\gamma \]  

(B.14)

and

\[ \tilde{X}_{2m+1}(\xi) = \frac{1}{N_{2m+1}} \int_{0}^{\pi} (\sin \gamma)^{-2\nu} \sinh[\theta \cosh \xi \cos \gamma] Y_{2m+1}(\gamma) d\gamma . \]  

(B.15)

Using Gegenbauer’s integral [11]

\[ n! \int_{0}^{\pi} e^{iz\cos \gamma} C_{n}^{\mu}(\cos \gamma) (\sin \gamma)^{2\mu} d\gamma = 2^{\mu} \sqrt{\pi} \Gamma(\mu + 1/2) \Gamma(n + 2\mu) z^{-\mu} J_{n+\mu}(z) \]  

(B.16)

one obtains

\[ \tilde{X}_{m}(\xi) = 2^{-\nu} \Gamma(1/2 - \nu) \sum_{n \equiv m \mod 2} b_{n} \frac{\Gamma(n - 2\nu)}{n!} (\theta \cosh(\xi))^{\nu} I_{n-\nu}(\theta \cosh(\xi)) \]  

(B.17)

where \( I_{\mu}(x) \) are modified Bessel functions of the first kind.

These functions increase exponentially at large \( \xi \) and the series (B.17) represent a solution of (A.15) of the first kind. As \( I_{n-\nu} \) and \((-1)^{n} K_{n-\nu}\) obey the same recurrent relations, the exponentially decaying solutions called solutions of the third kind (denoted in Appendix A by \( X_{m}(\xi) \)) take the form

\[ X_{m}(\xi) = 2^{-\nu} \Gamma(1/2 - \nu) \sum_{n \equiv m \mod 2} (-1)^{n} b_{n} \frac{\Gamma(n - 2\nu)}{n!} (\theta \cosh(\xi))^{\nu} K_{n-\nu}(\theta \cosh(\xi)) . \]  

(B.18)
